1 Introduction

The goal of this file is to pre-process the *Strongyloides papillosus* RNAseq dataset originally analyzed by Hunt *et al* 2016.

2 Pre-processing Methods Overview

Raw reads are aligned to the *S. papillosus* reference transcriptome (PRJEB525.WBPS14.mRNA_transcripts, downloaded from WormBase Parasite on 17 August 2020), using Kallisto. Kallisto alignments are imported into the R environment and annotated with information imported via the Wormbase ParaSite BioMaRT. Annotation information includes: *C. elegans* homologs/percent homology, UniProtKB number, Interpro terms, GO terms, and general Description information. Hunt *et al* 2016 establishes two distinct subclades from the four sequenced *Strongyloides* species: *S. venezuelensis*-*S. papillosus* and *S. ratti*-*S. stercoralis*. Thus, we also include annotation information for the appropriate in-group (here, *S. venezuelensis*), and a reference member of the out-group (*S. stercoralis*). Annotation information is saved as an R object that is passed to a Shiny Web App for downstream browsing and on-demand analysis. Note: Raw count data is be saved as a digital gene expression list.

Raw reads were quantified as counts per million using the EdgeR package, then filtered to remove transcripts with low counts (less than 1 count-per-million in at least 1 sample). A list of discarded genes and their expression values across life stages is saved. Non-discarded gene values are normalized using the trimmed

mean of M-values method (TMM, Robinson and Oshlack) to permit between-samples comparisons. The mean-variance relationship was modeled using a precision weights approach Law *et al* 2014.

A variance-stabilized, condensed DGEList object is saved; this file is passed to a Shiny Web App for downstream browsing and on-demand analysis.

3 Results/Analysis

3.1 Kallisto read mapping

This shell script checks the quality of the fastq files and performs an alignment to the *Strongyloides papillosus* cDNA transcriptome reference with Kallisto; to work, it needs to be saved as an .sh file in a folder containing required raw files. This script is reproduced here to demonstrate the QC and alignment process.

3.2 Import Kallisto reads into R

Import Kallisto transcript counts into R using Tximport. Counts are generated from abundance files using the `lengthScaledTPM` option. This code chunk is not evaluated each time, instead it was run once and an object containing the transcripts per million data is saved. In subsequent chunks, that file is loaded, and analysis progresses. The point of this is so that folks attempting to rerun this analysis do not need to have abundance files loaded on their local machines (and we do not have to upload abundance files to github).

3.3 Gene Annotation

Import gene annotation information for *S. papillosus* genes, including:

- *C. elegans* homologs/percent homology
- *S. venezuelensis* homologs/percent homology
- *S. stercoralis* homologs/percent homology
- UniProtKB number
- Interpro terms
- GO terms
- general Description information using biomaRt.

3.4 Generate Digital Gene Expression List

Next we generate a digital gene expression list that could be easily shared/loaded for downstream filtering/normalization. This code chunk generates a scatter plot of unfiltered and non-normalized transcripts per million data.

S. papillosus: Transcripts per million (TPM)

unfiltered, non-normalized data

S. papillosus RNAseq Dataset

3.5 Data Filtering and Normalization

The goal of this chunk is to:

1. Filter and normalize data
2. Use `ggplot2` to visualize the impact of filtering and normalization on the data.

3.5.1 Plot of unfiltered, non-normalized log2CPM data by life stage

3.5.2 Plot of filtered, non-normalized log2CPM data by life stage

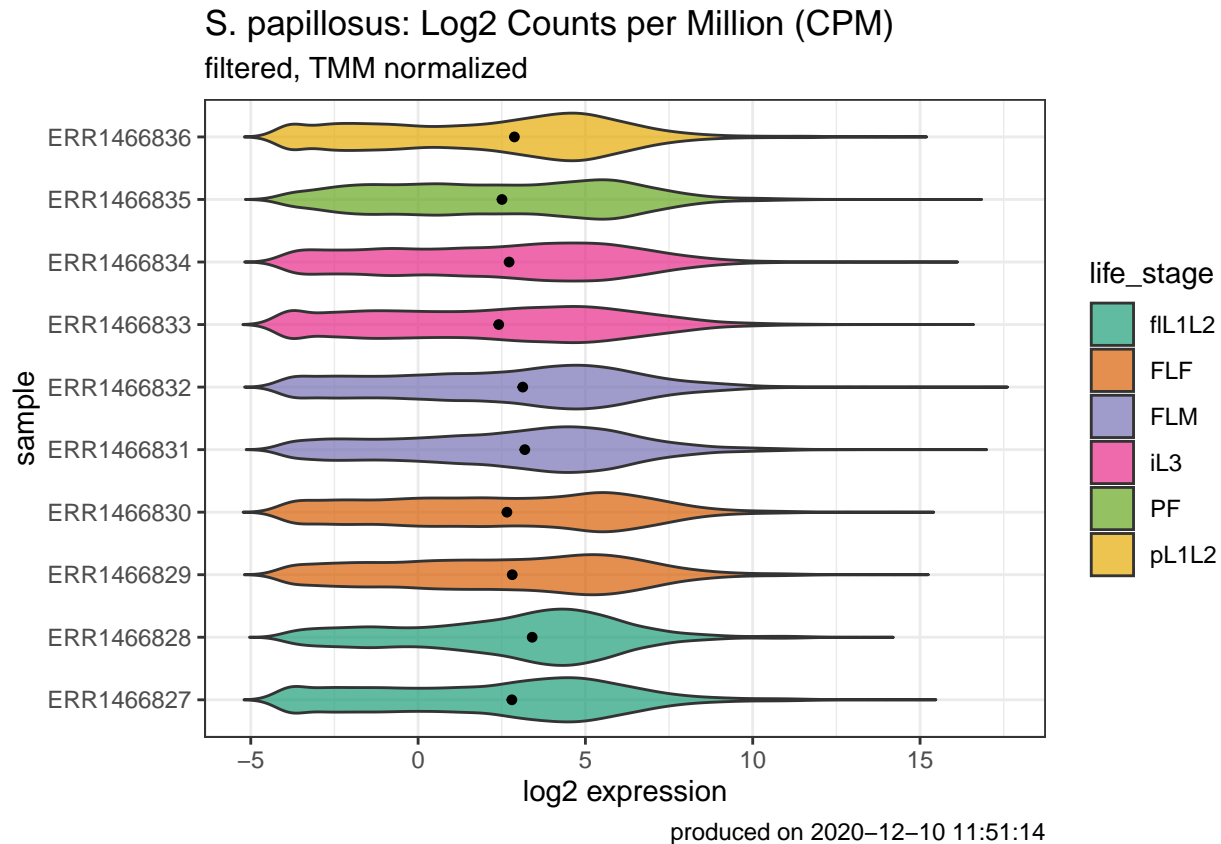

3.5.3 Plot of genes discarded by low-copy filtering step

The low copy number filtering step excluded a total of `dim(myDGEList.discarded)[[1]]` genes.

S. papillosus: Counts per Million (CPM)
genes excluded by low count filtering step, non-normalized

3.5.4 Plot of filtered, normalized log2CPM data by life stage

3.6 Compute Variance-Stabilized DGEList Object

This chunk uses a `DGEList` of filtered and normalized abundance data. It will fit data to a linear model for responsively detecting differentially expressed genes (DEGs).

3.7 Save Filtered Data and Annotations

Finally, we save data and annotations generated in code chunks above. We can separate these saving actions into two groups:

1. Data saved for downstream offline analyses, including the `SpRNAseq_data_preprocessed` file which saves filtered, normalized (but not voom adjusted) log2CPM values, gene annotation information, and sample information.
2. Files that are required inputs to the *Strongyloides* RNAseq Browser App, including:
 - i) a gene annotation R object (`Sp_geneAnnotations`)
 - ii) the variance-stabilized `vDGEList`, saved as an R object (`Sp_vDGEList`)
 - iii) a matrix of discarded genes and their raw counts (`SpRNAseq_discardedGene_counts.csv`) - this data is downloadable from within the Browser App
 - iv) a matrix of variance-stabilized gene expression data, extracted from the `vDGEList` (`SpRNAseq_log2cpm_filtered_norm_voom.csv`) - this data is downloadable from within the Browser App

By default, this code chunk will not be evaluated. To save the files described above, change the chunk option from `eval = FALSE` to `eval = TRUE`. These files are saved in an Outputs folder; in order to make them

accessible to a local version of the Shiny browser they need to be moved to appropriate subfolders within the App folder - the www sub folder (for .csv files) or the Data subfolder (for R objects). Stable copies are already located within those folders and do not need to be replaced unless the pre-processing steps change.

4 Appendix I : All code for this report

```
knitr::opts_chunk$set(echo = FALSE, message = FALSE, warning = FALSE)

# This script checks the quality of the fastq files and performs an alignment
# to the Strongyloides papillosus cDNA transcriptome reference with Kallisto.

# To run this 'shell script' you will need to open your terminal and
# navigate to the directory where this script resides on your computer.
# This should be the same directory where you fastq files and reference
# fasta file are found.

# Change permissions on your computer so that you can run a
# shell script by typing: 'chmod u+x readMapping.sh' (without the quotes)
# at the terminal prompt
# Then type './readMapping.sh' (without the quotes) at the prompt.

# first use fastqc to check the quality of the fastq files:
fastqc *.gz -t 14

# build index from the reference fasta file
kallisto index -i strongyloides_papillosus.PRJEB525.WBPS14.mRNA_transcripts.index
